CERTIFICATE

Certified that the work on 'Decision Support System for Defence Procurements' by Major S.S. Ahluwalia has been carried out under our supervision and has not been submitted elsewhere for a degree.

(V.M. Malhotra)
Lecturer
Computer Science Programme
I.I.T. Kanpur 208016, India.

R. Raghuram
(R. Raghuram)
Assistant Professor
Department of Electrical Engg.
I.I.T. Kanpur 208016, India.

ACKNOWLEDGEMENTS

I wish to put on record my deep sense of gratitude and sincere thanks to Dr. R. Raghuram and Dr. V.M. Malhotra for their invaluable guidance throughout the preparation of the thesis. Thanks are also due to Dr. B. Srinivasan for his guidance and interest shown in selecting the topic.

I shall be ever grateful to my Director Brig. N. Dayal, AVSM for sponsoring me to the M.Tech. programme.

Words fail to express my gratitude to my friends for the amusing company they gave and made my stay at IIT Kanpur a pleasant and memorable one.

Maj. S.S. Ahluwalia

ABSTRACT

This thesis describes the design and implementation of a computer based decision support system for parameter evaluation of Defence Procurement. The major components of information are identified and a systematic way of data structure validation and report generation is achieved.

The decision process is automated by integrating and storing data in a data base. DBMS-10 package available on DEC-1090 System at IIT Kanpur is used for creation of data-base.

The development and implementation of a Decision support system is discussed in detail. Various types of programs for load, update and Retrieval of data are developed. Necessary reports are generated to meet the users requirements. The decision support system is modular in design and implementation, offering the user a spectrum of specific capabilities. The user can use a specific modules without incurring the overhead of the other modules.

CHAPTER 1

INTRODUCTION

1.1 DECISION SUPPORT SYSTEM

The aim of decision support systems is to improve effectiveness of decision making by computer aids to the decision maker. A decision support system is a computer based system that is used on an ongoing basis by managers themselves, or their immediate staff, in direct support of managerial decision-making [1]. What has actually made decision support systems feasible and wide spread is the availability of software packages on computers that facilitate development of specifies user-defined DSS. A DSS is a vehicle to help managers to make more informed (and hopefully better) decisions [2].

The information produced by a DSS consists mainly of interactive-iterative reports and unstructured reports. In the search for supporting information in a specific decision situation, the user may be required to iterate particular reports. And adding and deleting selected variable deemed to be important components of the individual decision making procedure. Reports involving complex relationships such as portfolio management, budget analysis selection of competent vendor, analysis of typical items

(products) are some of the products of a DSS. However, these reports only represent a fraction of the potential output from a DSS.

Decision support systems have been developed as a result of managers trying to cope with decisions that include complex variable interactions. The ultimate object of a DSS is to help support a manager in making a decision.

An important characteristic shared by all computer-based information systems is the need for periodic restructuring, updating and expansion unrelated to simple maintenance and error elimination.

The three important agents as integral to the development of a DSS are :

- i) The client, who initially solicits the development of a system, specifies all performance criteria and often pays for the system.
- ii) The decision maker or user who actually interacts with DSS and to whom the support aspects are tailored.
- iii) The designer who specifies the details structure and capabilities of the system and is responsible for its implementation.

In some cases, the client and the user are the same individual, while at other times one person plays the three roles [2].

1.2 SCOPE OF THE THESIS

This thesis describes the design and implementation of a computer based decision support system for a defence organisation which is responsible for production and procurement of Electronic and Electrical items/equipments for Army and Navy.

A modular Data-base is designed and developed integrating and storing relevant information. Application Programs are developed and various reports are generated to meet the users' requirements.

The existing system maintains various records/file about Firms (suppliers) registered with defence, item/equipments projected for procurement, Projects earmarked for critical items/equipments, order placed for procurements, and inspection record of store inspected and released. The Firm record includes the list of products manufactured by the suppliers, the specification to which items/equipments are produced, financial position of firm and other details about firm, these are discussed in detail in Chapter 2. The other records contains information regarding projection and procurement of items/equipments and monitoring of critical items. Presently, these information are maintained on cards/files. The updating and retrieval of information to aid decision making is tedious and time consuming. There is,

therefore, a need for computerised data base to generate accurate and timely reports for making judicious decision in placing orders with competent firms so that defence store of the right quality materialise, as per laid down schedule at optimum price.

1.3 PLAN LAYOUT OF CHAPTERS

Chapter 2 describes the existing system and associated problems in maintaining and updating information.

Chapter 3 highlights the need for a data base, choice of programming feature. It also deals with the design methodology of a data base.

Chapter 4 gives in detail, the process of implementation of a data base using the DBMS-10 package available on DEC-1090 system at IIT Kanpur. This package is based on CODASYL 1971 Data Base Task Group (DBTG) proposals. Other features of the system like utility programs and back up strategies are also discussed.

Chapter 5 gives conclusion and recommendations for further expansion of the system.

CHAPTER 2

LITERATURE SURVEY OF EXISTING SYSTEM

The control flow chart of the existing system for demand and procurement of Electronic and Electrical equipments/items is given in Appendix A. Contollerate of Insp.Electr. (CIL) maintains a directory of competent suppliers (FIRMS). The capacity assessment of FIRMS is carried out by market survey teams and reports of their suitability for defence supplies or otherwise are forwarded to CIL through Regional Inspectorates. The control flow chart for capacity assessment is given in Appendix B.

Various records are maintained at CIL for suppliers to assess the potential of the FIRM for executing Defence Order. Selection of competent firms for floating tender enquires is a vital link in the chain of supply of defence stores. Following information about FIRMS registered with CIL for defence supplies is always available :

- i) Capacity Report
- ii) R and D facilities available with FIRM
- iii) Quality Control Method Adopted
- iv) Test Certificates/Qualification approval certificates, Limited Test Certificates/Limited Qualification Approval certificates issued to the FIRM.

- v) Prototypes successfully designed and developed by the firm
- vi) Financial position
- vii) Performance before and after placement of order
- viii) Range of products manufactured.
- ix) Misc. details like collaboration if any, Registration with DGS and D or Director of Industries etc.

Based on the above information each firm is given a separate notation and designation which summarises information on the firm.

An example of notation designation is

- LA₁-I₁R₁Q₁O₃F₁/N₆M₂/S₁U₁O₁P₀

This indicates that the FIRM is an Electronic equipment manufacturer ('L' is for Electronics), that it is recommended for placement of large orders (A₁), and that it is a large scale industry (I₁) with good R and D and Quality control facilities. So far it has not developed any prototype. It is financially sound. It has responded to tender enquires six times and the quotation of the firm was rejected twice. It has executed one supply order without delay and one with delay. There is one current supply order which is being executed. No supply order has been cancelled due to unsatisfactory performance.

A very careful assessment of the competence of firms to produce electronic goods to the desired defence specification is necessary. The main problem of the existing system lies in keeping track of items and equipment projected for procurement and monitoring of critical defence equipment (Projects).

In the present system, which is manual updating of information and report generation to aid decision making is time consuming and prone to human error. An inaccurate report may lead to wrong decision in selecting competent firm for materialisation of critical defence project. There is, therefore, a need for computerized information system to provide on line facilities to retrieve and update the data and generate accurate and timely reports for aiding decision making.

CHAPTER 3

ENVIRONMENT FOR THE PROPOSED DSS

3.1 NEED FOR DATA BASE

As explained earlier, it is essential to have a computerized information system for the organisation. There are two options available for the development of computerized information system.

1) To use conventional File Organisation Method :

In these methods the operational data may be kept in index, sequential or direct files. This method has two advantages.

- a) Implementation is easy, and
- b) Storage organization can be changed easily.

However, the retrieval of operational data, based on a multitude of purposes becomes really difficult and requires too many files to be maintained. This may lead to inconsistency of data. Also integration of the system with other information systems becomes a difficult problem.

2) To use DBMS :

A data base management system is a collection of stored data used by the application systems of an enterprise. It

provides centralized control of its operational data which is most valuable asset. Beside these, the data base management system provides the following advantages :

- a) Ease in system design and programming
- b) Independence of data and programs
- c) Concurrent usage
- d) Consistent and upto date data
- e) Protection and security of data
- f) Multiple host languages
- g) Data integrity can be maintained.

3.2 CHOICE OF PROGRAMMING LANGUAGES

The data base management system available on the DEC-1090 system can be used with FORTRAN, and COBOL. In this thesis COBOL has been used because it is best suited for record handling widely used for info. proc. application. It can be easily understood by any user who wishes to modifies certain application programs. The complexity of COBOL programming can be effectively controlled by employing structure of a programming concepts. We have decided to use COBOL with DBMS, so that the package can be easily implemented on any computer made available to the defence organisation in future.

3.3 DBMS-10 FEATURES

The DBMS package available on DEC System 1090 is a group of programs that enables an installation to create, access and maintain one or more data bases. It is based on 1971 CODASYL data Base Task Group proposals.

A data base is a collection of interrelated data records structured and linked so that run-units can access them without regard to the physical storage, medium. DBMS has two inherent advantages :

- 1) Removal of data description from the application programs.
- 2) Centralization of data management.

A CODASYL DBMS data base has the following additional advantages :

- 1) It allows to structure the data in a manner most suitable to each application program although that data may be used by many programs.
- 2) It allows more than one run-unit to concurrently retrieve the data in the data base even while a run-unit is updating it.
- 3) It provides a variety of search strategies that can be used on an entire data base or portions of it.

- 4) It provides protection of the data base from unauthorized access as well as from destructive interaction by run units.
- 5) It provides a number of ways in which one can relate the data records to each other.

3,4 COMPONENTS OF DBMS-10

DBMS-10 consists of the following components :

SCHEMA : The translator that processes the language used to describe the data bases. It also allocates and initializes the storage space for the data base.

DBMENO : A utility program for back-up and recovery of portion of the data base.

DB Info : A utility program that produces several reports such as cross reference listing and dumps of data base.

COBOL DBMS Module : The module of the Cobol compiler that processes data base accessing statements.

DBCS : The object-time module of DBMS used with FORTRAN and COBOL object time systems to access the data base.

For further details see [3].

CHAPTER 4

DEVELOPMENT AND IMPLEMENTATION

4.1 DATA STRUCTURE

An outline architecture for a data base system is shown in Fig. 1 [2]. The architecture is divided into three general levels: internal, conceptual and external. The internal is the one closest to physical storage, that is the one concerned with the way in which the data is actually stored; the external level is the one closest to the user that is, the one concerned with the way in which data is viewed by an individual user; and conceptual level is a 'level of in-direction' between the other two.

Fig. 2 shows the decision support system data base using data structure diagram notations. Data structure diagram is a graphic notation which uses two fundamental components - a rectangle and an arrow. A rectangle enclosing a name denotes an entity or record type. The second component is a directed arrow connecting two record types. The record type located at the tail of the arrow is called the owner record type and the record located at the head is called the member record type. This arrow directed from owner to member is called a set type and it is named.

The Data base structure shown at Fig. 2 shows a number of set types where the owner is the system. These sets are called singular set. Based on the types and frequency of retrieval and updating of various data, these singular sets are provided with sequential access of various record types for efficient processing.

4.2 SCHEMA

The Schema SSABAS.DDL for the decision support system is given in Appendix C. It defines the entire data base that is stored and available to all users. But an application program may need to view only some parts of the data base, and make some simple changes.

The statement 'Schema Name is SSABAS' names the schema. Statement following this statement are the area entries. All areas are named and privacy lock for exclusive update and retrieval for the opening of these areas may be specified. The schema defined will not allow simultaneous update although it is possible in DBMS-10 [2]. Simultaneous updates are costlier and are present when the data is accessed by multiple users simultaneously.

The decision support system data base is divided into six areas which are :

- 1) Inspection-Detail-Area
- 2) Item-Detail-Area
- 3) Project-Detail-Area
- 4) Projection-Area
- 5) Firm-info-Area
- 6) Man-Pro-Area (Manufacture product area)

There are a number of record types described in the data base. Item description for various data-items in each Record type is self-explanatory. One Record field for FIRM-Record is described in detail.

4.3 FIRM RECORD

Location Mode clause specifies the way in which record occurrences should be placed and retrieved. For this record type CALC is specified. CALC refers to key-to-address transformations technique (hashing). This clause specifies that FIRM-RECORD is placed according to the value of FIRM Name. The duplicate clause specifies that if any attempt is made to store a new but duplicate occurrence of FIRM-Record record, the system should reject the request and notify the application program of the rejection. By this clause storing of duplicate records is eliminated.

4.4 RELATION

The relationships between various record types, are described by means of the sets. Each set description names the set type, specifies the owner-record type and member-record type and gives detailed information on how occurrences of the set are to be ordered and selected. The singular sets are those in which the owner is the system and since the system is the unique owner, there can exist only one occurrence of such a set type. There are six singular sets in the DSS data-base. One set ALL-FIRM is selected for description.

4.5 ALL-FIRM-SET

After name of the set, the mode of set is defined as CHAIN. This indicates the mechanism for the manipulation of record occurrences within the set. It indicates the way member-record occurrences in the set are linked together and with the owner. The duplicate clause indicates whether duplicate records are permitted for the defined keys, and if they are, how they should be handled. In this particular set duplicates are not allowed. Next part of the declaration viz. OWNER clause specifies the name of owner record type and the declaration of system as owner denotes singular set.

The member sub-entry names the member-record type. MEMBER ~~is~~ clause names the member of the set. This is followed by a clause specifying permitted methods for a member record occurred from its membership to a set occurrence.

MANDATORY specification indicates that once an occurrence of FIRM-Record is placed in the ALL-FIRM set it may not be removed from the set occurrence without actually deleting the record occurrence. Automatic specification specifies that each time a new occurrence of firm-Record is stored in the data base it is automatically inserted into the ALL-FIRM set.

A complete description of the database scheme used in the propose DSS describes various set types, their corresponding owner and member record types and options used can be found in the schema listing given in Appendix C.

4.6 APPLICATION PROGRAMS

Various programs are written to aid loading, updating and retrieval of data. The programs are written only for the portion shown in dotted lines, the portion excluded contains information which is confidential in nature and also requires considerable amount of input data. However, since the schema converts the entire data structural diagram the load, update and retrieval could be expanded easily to cover the other Record types.

4.7 SYSTEM FLOW CHART

System flow charts are schematic representations of data flow in the system. Fig. 4.1(a) through 4.1(c) show in detail the flow of operational data and also how the data is retrieved and updated in the data base.

Various flow paths are discussed in brief. The application programs which carry out the different data base operations are given.

i) Loading Path

Fig. 4.1(a) shows the flow of master data into the data base. The input data files are created on desk (EDITIN.DAT) which are edited by corresponding programs (EDIT.CBL) for validating. Two files are created by EDIT.CBL, ERROR.LST and INPUT.DAT. If data is found to be valid INPUT.DAT file is created and ERROR.LST file remains empty. But if data is erroneous then ERROR.LST file contains list of errors detected and INPUT.DAT is empty. The procedure for preparation and editing of data is describe in subpara 4.8.

ii) Update path

Fig. 4.1(b) shows the information flow paths for operational data during various updates operations. The bulk of data will be loaded into data base with the help of LOAD programs but user may require programs to update the data loaded by adding new information or deleting absolute

information loaded initially in the data base by load programs.

The update programs provides the users on line facility to update data base as and when required. The UPDAT programs are interactive and access is provided for modifying any data in data base. The update programs are discussed in sub-para 4.10.

iii) Retrieval path

Fig. 4.1(c) shows the flow path during the retrieval of information by the user. The user may like to generate various reports to aid decision making, this facility is provided with the help of on line interactive Retrieval programs. Various types of reports are generated by Retrieval program about items supplied by manufacturers, list of firms who are capable of producing desired items, the vendor rating of firm and details about firms in coded form. The retrieval procedure is explained in detail in para 4.11.

4.8 DATA PREPARATION AND EDITING

Information on various data elements should be entered in the corresponding files. Once the data file is created, the Edit program should be run to check the validity of the data. If any data is found to be invalid or erroneous, the corresponding error message are given in the corresponding

error list for further correction. If the data file is found valid, then the corresponding input data file will be created by the edit program, which will be used by the corresponding load program to store data in the data base. Only one Edit Program is written to check the validity of Item-Record in detail. This program can be expanded when actual data is used.

4.9 LOAD PROGRAMS

Load Programs loads the various data items into data base. It sets various link required in storing of data which are used for retrieval of information and report generation. The design of data base is modular and relevant information can be loaded into data base by accessing only the specified record fields.

The modular design makes data base cheaper and efficient in loading and retrieval of information. It is therefore desirable to use number of load programs depending upon the requirements of ^{the} user. Three load programs LOAD1.CBL, LOAD2.CBL and LOAD3.CBL are written to load different record fields.

LOAD1.CBL loads information about Firms, Projects, items supplied and Range of products manufactured by the suppliers. The information about Firms includes past performance of firm, Quality control arrangement, R and D facilities, financial position, vendor rating of firm and firm code which gives

detail information about firm in coded form. The project information includes quantity on order, value of order, date for submission of prototype and number of extention given for meeting delivery schedule. The information about item supplied in past with part-number of item, range of products manufactured by the supplier, with rate of production and specification is also loaded by this program.

4.10 UPDATE PROGRAMS

When only a few records are to be entered or deleted from data base on line programs are useful. The update programs provide on line facilities to update the information loaded in data base. The user can add new information or delete an absolute information from data base by running UPDAT program. The program is interactive and user can access any record for addition or deletion of information. Self explanatory questions are asked by the program and user is asked to provide the information about update of record fields. UPDAT program provide the facility to correct the data erroneously given by the user before updating. Once the data is validated the program stores the data and sets the appropriate links for records. The user is then informed about the successful loading or deletion of information. Wrong deletion of record may be fatal, program provides the facility of confirmation by user before deletion by printing the appropriate record. The record is deleted only when

confirmed by the user. The UPDAT program provides facility to add or delete Firm, Item, Project and manufactured products records. The program can be expanded to include more record depending upon the need of user. A typical run of up-date program is given at Appendix E.

4.11 RETRIEVAL PROGRAMS

INFO.CBL Program

Five types of quiries are available to retrieve data about firms, items supplied, projects in which the firm is involved, manufactured products. The following reports are generated when required by the user.

- 1) By giving the CAT-PAT-ON the user can get the names of firms who have supplied this item in the past, vendor rating of firms and important def items manufactured by these firms.
- 2) By giving the name of the project, the user can get the names of firms which are executing this project, their postal address and latest bottle necks, if any.
- 3) By giving the name of any item/equipment the user can know if any supplier registered with defence exists and if so, its name and address.
- 4) By giving the name of project and the item user can get names of firms which are involved in the project and also producess the required item.

5) By giving the name of two items/equipment, the user can get information about firms who are manufacturing these items/equipment and are registered with defence.

Many more useful reports may be generated by expanding the Retrieval program depending upon the need of user. A typical run of retrieval program is given at Appendix F.

4.12 BACK UP STRATEGY AND RECOVERY

When an updating run-unit accesses the data base, it has the potential of making damaging changes to the data base. So DBMS provides means to remove the changes made during the execution of a run unit. This is done by the use of the Journal file. A BEFORE image is a copy of a data base. CBCS writes a BEFORE image of that particular page in the Journal file. For bringing back an old copy, an utility program called DBMEND is provided in the system. For decision support systems disk journal is specified as a list of commands to be given for recovery are given in Appendix D.

CHAPTER 5

CONCLUSION AND RECOMMENDATIONS

5.1 CONCLUSION

The basic role of a decision support system is to ensure that reliable information is generated and exchange between personnel in safe, timely and cost-effective ways. It is absolutely necessary that central control be established for decision making and monitored through all phases of the life cycle of the data base designed and developed for decision support systems.

An attempt has been made to design a decision support system for a defence organisation responsible for production and procurement of Electronic and Electrical items/equipments for defence forces.

Various loading programs for initial loading and regular updates have been developed. Various updating feature like adding a New FIRM (supplier) new item, new project, new manufacturing products have been provided.

Only one edit program is developed for validating input data (for item-record only) other edit programs could be prepared using the actual input data.

DBMS-10 package available at IIT Kanpur has been used to design and develop the decision support system. It will need minor modifications if used with other DBMS packages.

The decision support system designed ^{as} developed will help the organisation in generating accurate and timely reports to aid decision making. The maintenance cost of system designed will be much cheaper in terms of man power and time.

5.2 RECOMMENDATIONS FOR FURTHER WORK

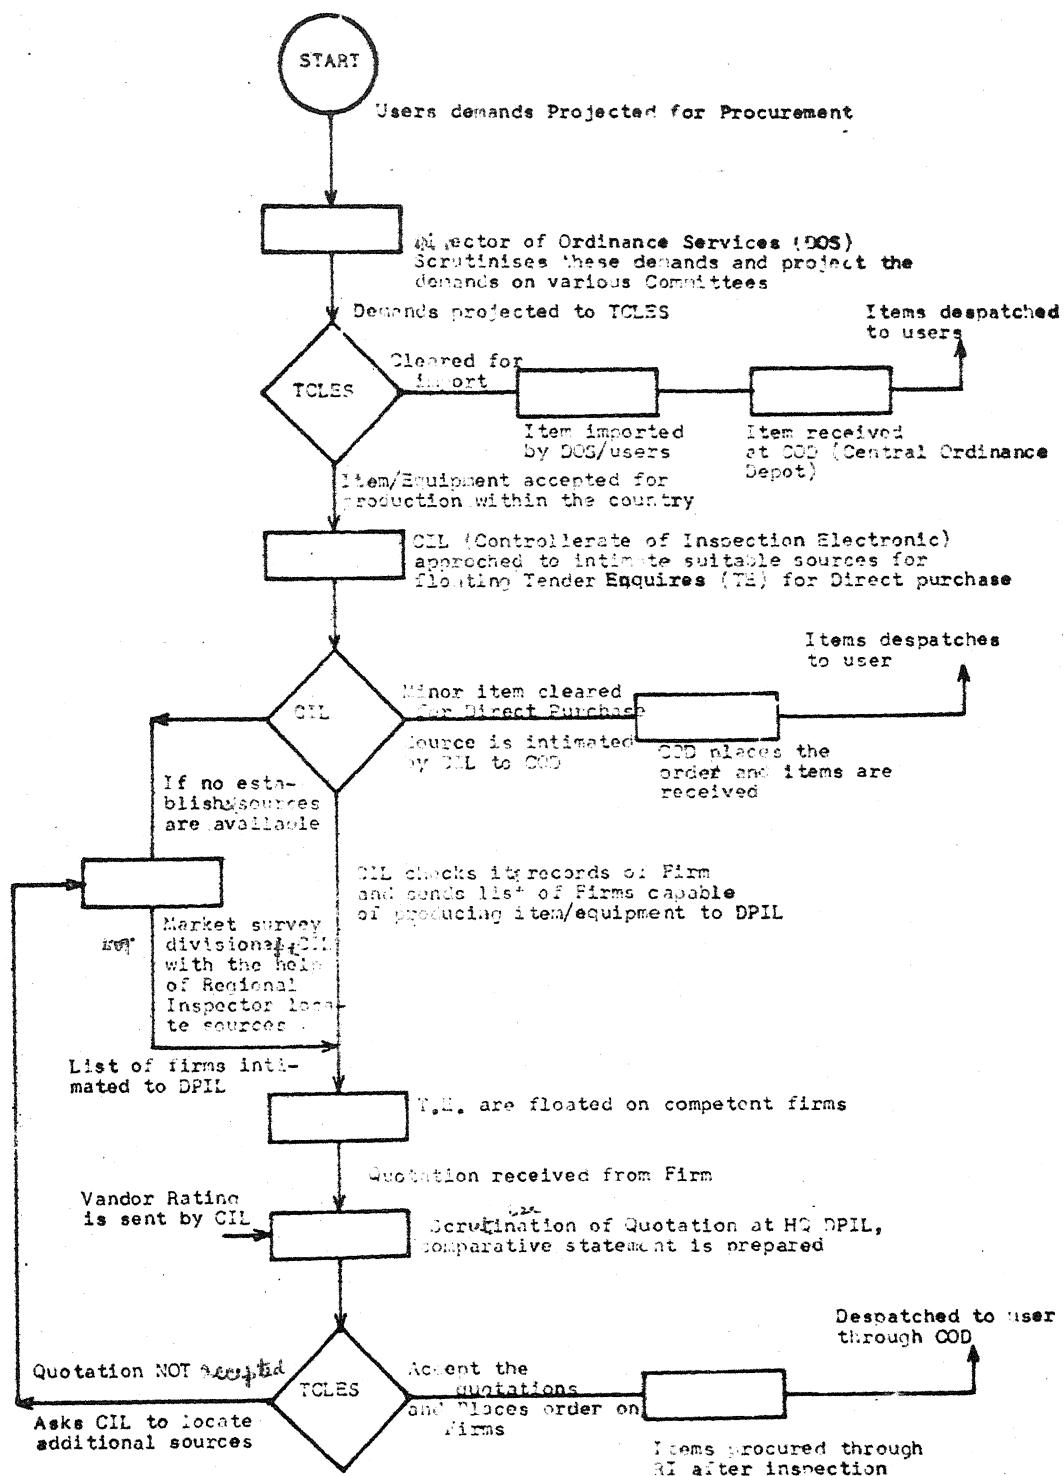

The decision support system designed will be helpful in decision making for selection of competent firm for placing defence orders. The data base of the system can be expanded to include some more functions like import substitution, specification comparison, digitalisation and storing of drawing in data base.
